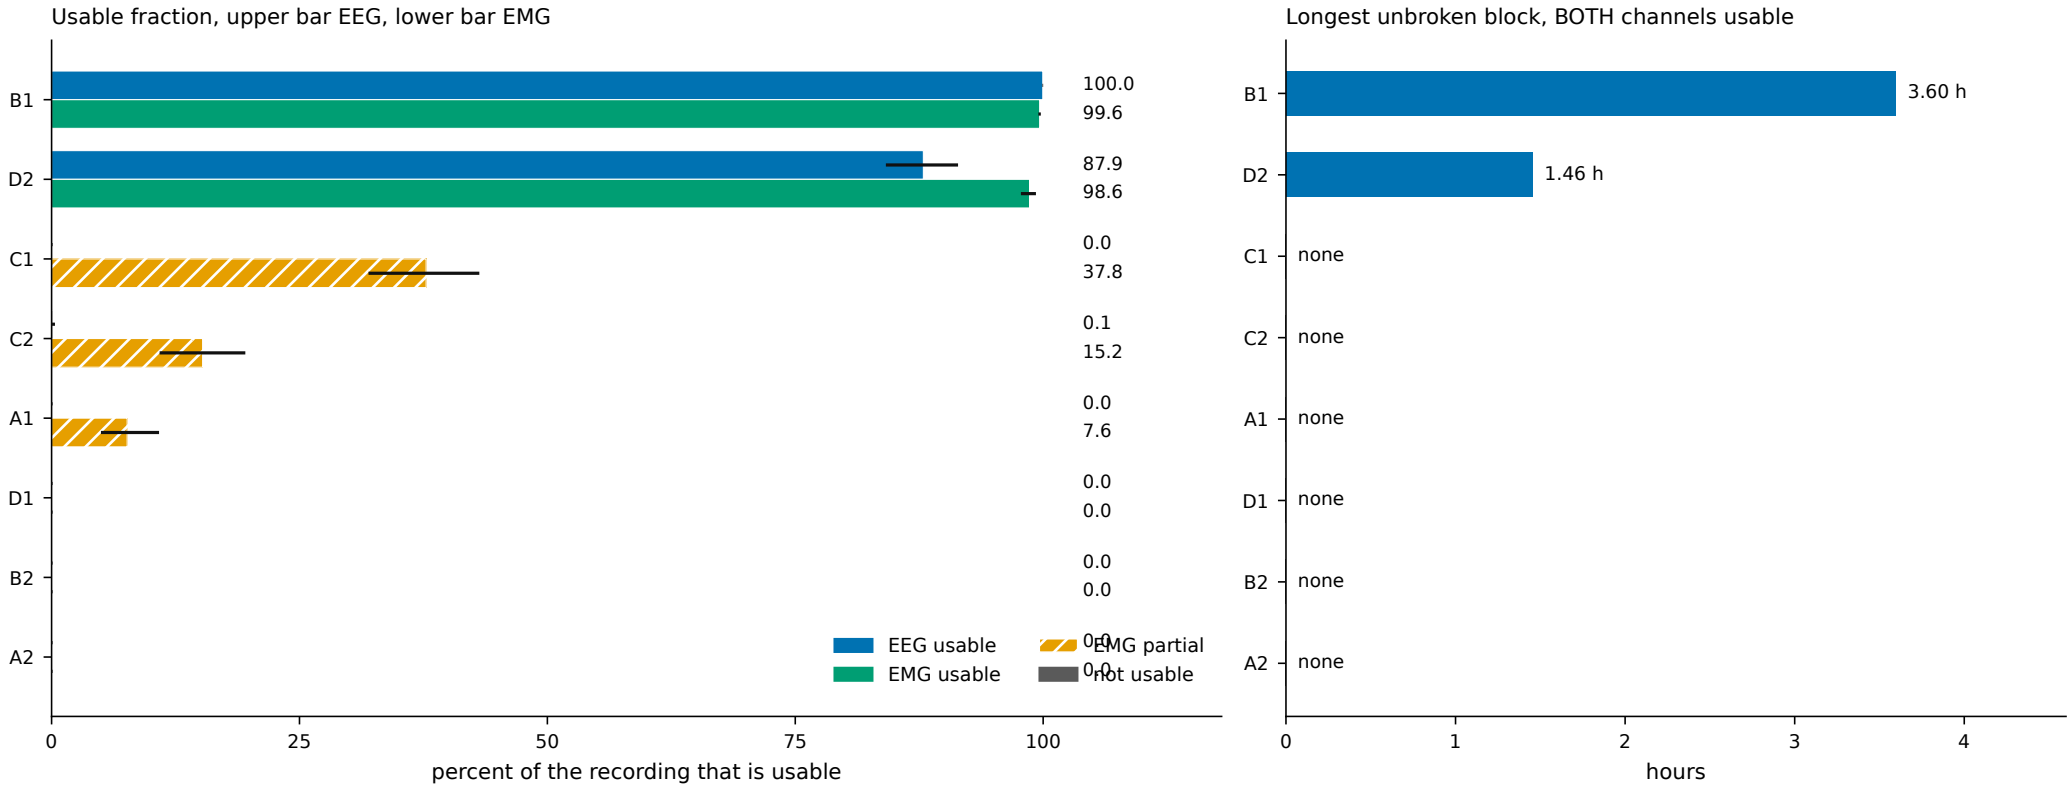

Figure 2. Outcome of the 23.66 hour overnight recording of 6 to 7 August 2026, all eight positions

Criterion, pre registered before the recording existed, applied per 10 second epoch: 60 Hz amplitude below the 1st percentile of the wire free floor (415.0 microvolts here), root mean square between 10 and 150 microvolts, and zero saturated samples. n = 8517 epochs. Black bars are 95 percent BLOCK BOOTSTRAP intervals over contiguous runs of epochs. A binomial interval would be far too narrow: contact persists for tens of minutes. For D2's EEG channel, the one where the interval carries any weight, the effective sample size is about 1088 epochs rather than 8517, and the interval is 5.3 times wider than a binomial interval on the same data would be. Falsification passed: the wire free floor scores 0.00 percent and the A2 position, which holds a cut cable and no animal, scores zero. Hatching marks the partial category so the figure survives grayscale.
