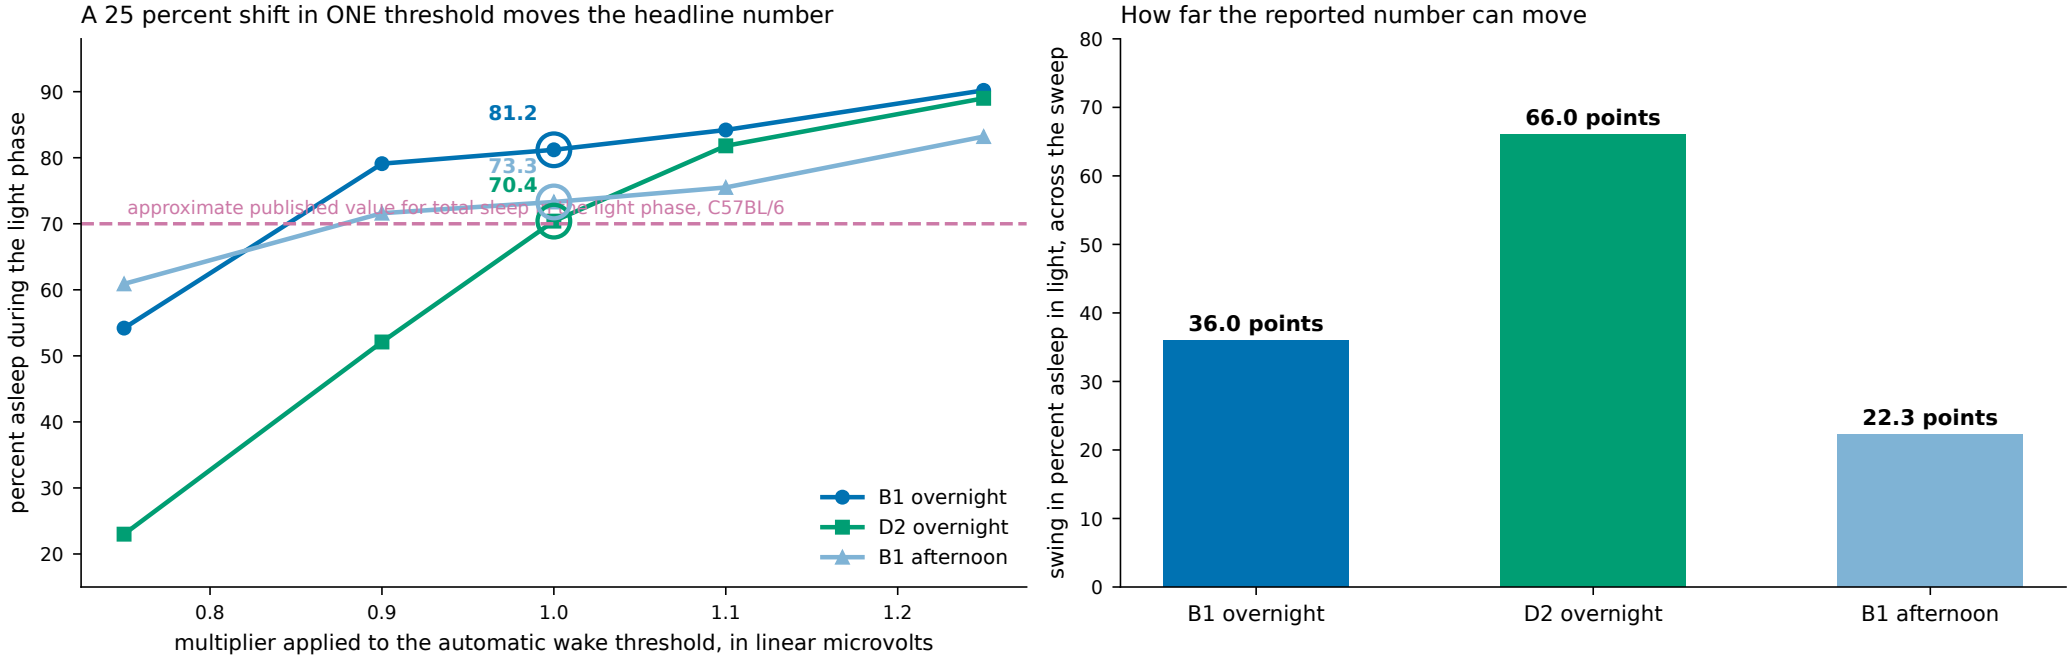

Figure 6. Why the agreement with the literature is NOT independent confirmation

The wake threshold is fitted separately for each animal by Otsu's method on muscle amplitude. Sweeping it by plus and minus 25 percent in linear microvolts moves the percentage asleep in the light phase of D2 from 23 to 89, so the published value is reachable from almost anywhere in that range and the reported numbers must always be quoted with this swing beside them. NO SHADED REFERENCE BAND IS DRAWN, deliberately. An earlier version of this figure drew one from arithmetic that corresponds to no published interval: the dispersion this project holds is for NREM alone, 62.0 plus or minus 7.8 percent per 12 hours, whereas the quantity plotted here is NREM plus REM. The dashed line is a single approximate literature value for total sleep and carries no interval. A threshold this sensitive also means the muscle amplitude distribution has no clear valley between sleep and wake, which is the more useful finding. The fix is human scored ground truth.
